

MECANISME PINEALE RESPONSABILE ÎN DECLANȘAREA PUBERTĂȚII

Prof. univ.dr. **Lazăr Onisâi**
Universitatea Transilvania din Brașov,
Facultatea de Medicină

Epiphysis gets its shape as an diecefalic primordium, but its development is slow. After birth it has a histological aspect where the photoreceptor cells are allmost typical. In the first years, the number of the cells are increasing and the epiphysis is made of 2 different cells type. The aging of the epiphysis is progressive and will be over at the end of puberty.
